Lunar Energy

Remote

Operations BI Engineer Contractor

Building the operating layer behind a fast manufacturing scale-up.

Dear Lunar Energy Hiring Team,

The dashboard is not the deliverable. The operating decision is.

Lunar is scaling a Gen2 production line and a wider supply base while operational data is spreading across manufacturing, quality, supply chain and fulfillment. The role therefore calls for more than a BI developer: it needs someone who understands the factory decisions beneath the metrics and can turn incomplete requests into tools people actually operate. That intersection is the core of my profile as an industrial engineer, Supplier Quality Engineer and data/automation builder.

At Magna International, I developed a complete SQE BI and workflow system that traces electronic and metal components from nomination through Safe Launch and SOP. Across six control modules and four lifecycle gates, it aligns owners, milestones, PPAP/DVP evidence, critical parts and open issues, then uses KPI views and automated notifications to keep global supplier programs on track. Earlier at Stellantis R&D, I paired a structured Databricks model with a Python application to detect and prioritize E-BOM/M-BOM anomalies, reducing a two-day treatment cycle to under three minutes with 100% reliability across the defined test cases.

I would bring that same operating discipline to Lunar's OEE, yield, downtime, cycle-time, throughput, shortage and fulfillment questions. My current toolkit centers on Power BI, Python, SQL, Databricks and workflow automation. Grafana, PostgreSQL and the Atlassian/Google APIs are a focused platform transition on top of the metric design, data modeling and exception-control fundamentals I already use—not a substitute for them. I will be direct about that ramp-up and equally direct about the value I can start creating from the first operational workflow.

01 / SEE THE OPERATION Decision-ready manufacturing visibility Define OEE, yield, downtime, cycle time and throughput around the recurring decisions they must trigger—not as passive reporting.	02 / CONTROL EXCEPTIONS Owner, risk and next action in one loop Turn shortages, critical parts and open issues into traceable queues with ownership, due dates, evidence and automated follow-up.	03 / CONNECT THE WORK From fragmented sources to one operating layer Use SQL, Python and system integrations to replace manual refreshes and status chasing with governed, reusable workflows.
--	---	--

6 modules SQE control system nomination to SOP	4 gates lifecycle traceability through Safe Launch	< 3 min validated BOM treatment previously two days	900 series forecasting and replenishment tested
--	--	--	---

FIRST 30 DAYS / FROM AMBIGUITY TO AN OPERATING LOOP

01 MAP Stakeholders, decisions, KPI definitions and source ownership across manufacturing, supply chain, quality and fulfillment.	02 BUILD First decision surface, data-quality checks and an exception workflow around the highest-cost recurring operational question.	03 OPERATE Validate adoption, automate refresh and alerts, document ownership, then prioritize the next workflow by measurable value.
---	--	---

Lunar's mission makes this work consequential: every clearer constraint, faster exception decision and better-controlled production handoff helps move dependable clean-energy hardware into more homes. I would welcome a conversation about the first recurring operational decision you want this contractor to improve—and how I would make its data, ownership and action path visible.

Sincerely,

Rida Melkaoui
